AIRLINE *Telephone Typewriter* SERVICE

WITHOUT REBOUND -GRÜSS

SEVEN TONS! AS EASILY AS SEVEN HUNDRED POUNDS

CUSHIONING the shock of a seven ton load, smoothly... without rebound, that is the job Grass does for America's largest land plane, every takeoff, every landing, every day.

On small planes too, Grass struts eliminate landing hazard and rough ground worry. The smooth, yet lightning like action of these aircraft shock absorbers lets no lump pass the wheels. A Grass equipped plane will land and taxi smoothly, without rebound.

Grass retards depreciation. Grass, without rebound, counteracts landing vibration with its air and oil action. In addition, Grass struts now come to you as complete units, streamlined in our factory and shipped to you complete with fittings ready for instant installation in your plane.

Investigate now the life lengthening possibilities of Grass.

NEW NAVY CURTISS XPIC-4 3 SEATER CARRIER FIGHTER

CURTISS MARINE TROPHY RACE

The Navy speed clinic, completed its season by service type aircraft. All the fighting planes in this year's race, and the winners for the past three years, have been Curtiss planes.

THE ARCTIC PATROL

A 3400 mile journey across the continent and back, completed last January under terrific weather conditions by 18 planes of the Army's First Pursuit Group. All were Curtiss P-12's, powered with Curtiss D-12 engines.

AIR CORPS MANEUVERS

The annual "war games" of the Air Corps, participated in last April by 160 of the Army's finest service type aircraft. More than half of these were Curtiss planes powered with Curtiss engines.

NEXT YEAR --

Next year, when the Navy holds the Annual Curtiss Marine Trophy Race, or the Army sends an Arctic Patrol on a grueling mid-winter cross-continent jaunt, or the Air Corps Maneuvers are held, the performances and records will be still finer than the splendid achievements of this year. For in military aviation, there can be no compromise with progress. Superiority must be maintained at all cost.

Already, since January 1935, Curtiss has produced and delivered four new types of military aircraft to the Army and Navy. These include the remarkable XP8C-4, a two-seater carrier fighter for the Navy; the XP-10, a single seater Army pursuit with a top speed of well over 200 miles an hour; the O-26, Army observation plane, with still higher performance than the standard Falcon; and the XT-4, a new basic training plane for the Army Air Corps. Each is superior to types now in service. And in the Curtiss engineering laboratories, still others are under development—development that goes on unceasingly to maintain our aerial supremacy.

A DIVISION OF CURTISS-WRIGHT CORPORATION

AND

THE AVIATION CORPORATION GOES STANAVO

Flying 20,000 miles a day in all weather from the Gulf to Montreal and from El Paso, Texas, to Boston, Mass., the Aviation Corporation, through its subsidiary, American Airways, Inc., operates 5 participating corporations with 21 subsidiaries. The combined routes of these companies cover 9,128 miles, making the largest air transport system in America. Over many routes 3 flights a day are made. Naturally the question of what engine oil the 259 planes of the Aviation Corporation should use is highly important. Safety, overhead and availability all must

be considered. After extensive tests the Aviation Corporation found that Stanavo Aviation Engine Oil met every lubrication requirement . . . plus that, they found that Stanavo is available everywhere, throughout the world.

Recently, the Boeing System adopted Stanavo . . . many other leading aviation companies have already done so—and now the Aviation Corporation has gone Stanavo. If you own or operate one or many airplanes you cannot do better than follow suit. Get in touch with one of the oil companies listed below today.

The GOOD MECHANIC'S CHOICE

for 33 years

For general all-purpose work, mechanics call this an exceptionally fine drill. It's easy to understand why. Powerful universal motor for A, C, or D, C, operating at 450 R.P.M. UNDER LOAD. Chrome nickel steel gears, hardened, running in grease. Heavy duty SKF Ball Bearings, etc. Over 1000 balanced and easily handled. Only 14½ pounds in weight.

Like the big brother above, this steady little drill (only 9½ pounds) is built to stand up under long, continuous service at its full rated capacity of 1,000 R.P.M. UNDER LOAD! In addition to the features listed above, this drill also includes: indestructible telescopic housing. Quick make, quick break trigger switch. Removable 1-toner anvil and handle housing. Three gear, semi-automatic chuck for straight shaft drill bits, etc. Complete with twelve feet of flexible rubber-covered cable, guard and universal public 3-phase attachment plug. Get the new U. S. Catalog.

GREEN RAMPAS MOUNTAIN PEAKS

PLAINS vast as the rolling sea... impenetrable fastnesses of the jungle depths mountain peaks that have defied the hardest explorer—all have been conquered by the airplane. Yesterday—barely reached in six weeks' time... today just a few hours distant. For a squadron of FLEETSTERS operated by the New York & Buenos Aires Line Inc. are penetrating the interior of the Argentine establishing fast mail and passenger communication—and opening new markets for North American industries. The FLEETSTER—equipped with a useful load of 2,000 pounds and a cruising range of 400 miles at 145 miles an hour—offers equal opportunities to transport operators throughout North America.

THE FLEETSTER

Consolidated Aircraft Corporation, Buffalo, N.Y.

CONSOLIDATED AIRCRAFT
CORPORATION Buffalo, N.Y.

—and he named it the "LOCKHEED MOUNTAIN"

Captain Wilkins—pilot of both the Arctic and Antarctic expeditions—stands by the Lockheed plane which he used in his historic flying polar flight.

It stands at the bottom of the world, majestic and perennially snow-covered... Captain St. George Herbert Wilkins was the first man ever to sight the Antarctic peak and he named it the "Lockheed Mountain"—in honor of the ship from which he discovered it.

Captain Wilkins chose a Lockheed for his polar expeditions by air because he knew "it was the finest ship available." His first was over the top of the world on a 1,200-mile non-stop flight from Pease Harbor, Alaska, to Spitzbergen. Later he took it, as one of two Lockheeds, to the Antarctic to explore the vast, unknown wastes that surround the South Pole.

On all of his polar flights—where the failure of any vital part would have meant disaster—Captain Wilkins' Lockheeds performed perfectly. They were flown, on wheels, in and out of ports—in temperatures which ranged from 132 degrees above zero to 54 degrees below! And today Captain Wilkins' original Lockheed, the second ever built, is still in active service.

The record of Captain Wilkins' ship conclusively proves the sturdiness, safety—and the speed—that are built into every Lockheed.

ROBERTSON *shares its* HANGAR BUILDING *experience*

GAIN YEARS OF EXPERIENCE BY WRITING A LETTER

Call in your stenographer, dictate a letter about any problem you may have about hangars or other airport structures and send it to the Engineering Department, the H. H. Robertson Company, Pittsburgh.

Without charge and without obligating you, the Robertson engineers will tell you what their experience has been with similar problems.

You will find that these Robertson engineers have probably had a definite experience with some airport problem exactly like yours, for they have been continuously engaged in the design and erection of hangars since the early days of the war . . . in the United States, Canada, Mexico, South America, England, Spain, Greece, Egypt, India, the Philippines, Hawaii, Panama and many other parts of the world.

They will be glad to give any recommendations about your problems that this world-wide experience may suggest.

H. H. ROBERTSON COMPANY
Pittsburgh, Pa.

The illustration shows about one of the hangars of Pan American Airlines, Inc., at the Atlantic Ocean, Norfolk, Va. More than 12,000 square feet of Robertson Patented Metal (SR-16) was used in the roof and walls of this hangar.

the GREAT LAKES SPORT-TRAINER
should outsell all other ships!

HERE, at last is the ship Dealers have been waiting for! An outstanding flyer—a good looker—a ship that's the personal favorite of pilots everywhere. A quality ship that's priced so low that you can confidently look forward to volume business, yet one that allows you generous discounts, too.

This is the same ship in which Tex Rankin performed 34 outside loops—without loosening a single brace wire. The same ship that holds the non-stop economy record from Canada to Mexico. The same ship in which the altitude record for women was recently broken.

There's not a sweeter appearing plane on the market. A two-place job, either

open model or convertible coops. The sort of ship people are proud to be seen flying—the sort you'll be proud to show off to prospects.

You can make money with a Great Lakes franchise. Great Lakes Operator-Dealers are selling Great Lakes Sport-Trainers right now—they are running their schools at a profit—they are maintaining service hangars that bring them a steady income. You can do the same thing.

Write us—now. Tell all about your set-up. Tell something of flying conditions at your home field. Let's get together and make money for and with each other in 1933! Address your letter (send it air mail) to Great Lakes Aircraft Corporation, Division J-13, Cleveland, Ohio.

KELSEY-HAYES
AIRPLANE WHEELS
UNIVERSALLY CHOSEN

INTRODUCING LOW PRESSURE

U. S. ROYAL AIRPLANE TIRES

United States Rubber Company now introduces a most advanced and practical improvement in tires for aircraft. These low pressure tires provide increased safety in flying operations through easier landing, and ground performance is much improved. Larger ground contact permits flying from soft and muddy fields with safety.

These tires are scientifically designed and built by long-established standard production methods, basic manufacturing processes, using Web-Card construction and Flatband building, are incorporated—thus giving greatest strength of tire with minimum weight.

Aerodynamic drag, weight and cost of the new tire and wheel assemblies are comparable in every way with present high-pressure equipment. The sizes now available are 6.50-10, 7.50-10, 8.50-10, 9.50-12 for landing wheels and the 5.00-4 for tail wheels. A full line of all sizes will shortly be available.

CORSAIRS

IN FOREIGN WATERS...

with the ASIATIC FLEET

smooth expert undergoes no strain which in any manner approaches it.

Corsairs are designed not only for extreme maneuverability but for a ruggedness far beyond ordinary requirements as a strut-brace that enables them to meet demands few planes of any type are called upon to meet. Their performance has made them the delight of all naval pilots who fly them. CHANCE VUGHT CORPORATION, Hartford, Connecticut. Division of United Aircraft & Transport Corporation.

In duties have been among the hardest any naval plane can undertake—observation.

As a naval observation plane it has been exhaustively equipped into the air from the ship. Landings are made alongside the ship. Then the plane is picked up by a crane and swung aboard.

Such operating is naturally a severe strain on an airplane. A ship making ordinary take-offs from a

SERVICE is the United States Navy may mean duty anywhere in the world. This is as true of airplanes as of men and battleships.

Corsair No. A-7009 has seen most of its service with the Asiatic Fleet—first with a Light Cruiser Division on board the U.S.S. Trenton, later with the Memphis.

CHANCE VUGHT CORPORATION

Are You Compressed Air-Minded?

While the public is becoming "air-minded," Airport operators and Airplane manufacturers are rapidly becoming conscious of the tremendous value of compressed air to them.

As the Airports, compressed air is spraying paint and dope, clearing engines, blowing out gas and oil lines, inflating tires, etc. Plane Manufacturers are using it to operate all kinds of pneumatic tools as well as for paint and dope spraying.

Compressed air is so convenient, so flexible, so economical!

Model #7

Water cooled. Four sizes from 4 to 24 in. 3/4 x 5/8. Displacement from 15 to 120 cu. ft.

Model A

Air cooled. Six sizes from 2 1/2 to 15 in. 4 1/2 x 3. Displacement from 1 to 27 cu. ft. Light and heavy air V type pattern if desired.

Model G-18

Two-stage, fully automatic. Displacement, 31 cu. ft. with 112 P. motor, 44 cu. ft. with 117 P. motor, 62 cu. ft. with 121 P. motor. Tach. 20 x 46, 67 gals.

Quincy Compressors

are the very strongest air compressors value today. They represent the best engineering brains in the industry—and the "factory ideal" measure right up to the engineering.

Quincy Compressors are economical to operate; economical to maintain; and they deliver all the air and all the pressure their specifications call for.

Furthermore, every Quincy Compressor is factory tested—thoroughly capable of maintaining the right air pressure for your work and of servicing it after installation.

Get all the facts about Quincy Compressors. Write or use the coupon.

The General Electric supercharger consists of an impeller, or wheel, located in a specially designed passage between the compressor and the intake manifold. It is usually driven by gearing to the crankshaft of the engine. The results are increased power through increased pressure in the intake manifold plus improved representation and distribution of the fuel mixture.

THE G-E SUPERCHARGER A TRIUMPH OF ENGINEERING SKILL

THE IMPELLER, or wheel, is the heart of the G-E supercharger; the very life of the engine depends upon it. Rotating speeds of 30,000 rpm. are not uncommon to this small wheel. But to withstand the tremendous forces which are met at such speeds requires the most careful consideration of every detail in its design and construction. General Electric engineers have specialized every process in its manufacture, from the selection of raw material to the balancing of the finished product. The skill and technique required through the building of thousands of high-speed turbines and compressors have contributed much to the success of more than 8,000 G-E superchargers now in service. We invite your interest. Write us—General Electric Company, Schenectady, N. Y.

AVIATION

THE OLDEST AMERICAN AERONAUTICAL MAGAZINE

A McCLURE-HILL PUBLICATION — ESTABLISHED 1893

EDWARD F. WARNER, Editor

VOLUME 111, . . . June 7, 1930 . . . NUMBER 10

Taking Prohibitions Off Foreign Trade

MOST of the civilized countries of the world now license civil aircraft, and impose some sort of amphibious requirements. All of the 27 nations that have ratified the International Air Navigation Convention have pledged themselves to do so, and to erect some reasonable mechanical and aerodynamic standards from all the machines that fly the national colors. In most of the countries where aviation has been very highly developed, including all of the "great Powers," the preliminary tests include an inspection of the plane during the process of construction. The fitting of foreign-built planes then becomes impossible, and foreign trade in airplanes is swept off the boards at a stroke, except for exports of military craft and shipments to countries that have no industry of their own and cannot afford to be unduly severe in their regulations.

Under a strict application of the rules, no airplane can well qualify for an American license without having been built here. Still more certainly, no airplane can be licensed in Great Britain, without special derogation from the letter of the rules by courtesy of the government or by international agreement, unless it is the product of a British factory. All the evils that economists find in high tariffs are amply exemplified in this complete stoppage of trade—a stoppage incidentally that contravenes the spirit if not the letter of the recently-framed League of Nations Convention on Prohibitions and Limitations on the International Exchange of Goods.

There are, of course, some waters raised in favor of these international barriers. The same arguments that are aligned behind a tariff opposed and reflexively protective are trotted out in support of expenditures to bar all imports. There are American manufacturers who consider that the exclusion from the American market

of French and German airplanes, made with steeper labor than ours and in some instances with special advantages afforded by their governments, should be the first consideration, and that it does not matter how the exclusion is accomplished. There are no doubt leaders in the British industry, to take a single foreign example, who feel that the market in the British Dominions should so far as possible be reserved for British planes, and that the exclusion of the British machines from the United States will be a small price to pay for the privilege of keeping the American product out of the Empire.

No doubt such groups exist in both countries, and in other lands as well, but they are all wrong. Should their views prevail, they might gain some temporary advantages, but in the long run they would have occasion to regret it. There are no recorded exceptions to the rule that a sensibly free flow of trade is in the general interest. Our foreign readers may feel that the statement comes with questionable grace from a nation outward of a high tariff, but we make it with conviction. To attempt to treat aircraft as constituting an exception is to require a series of exceptions and counter-exceptions that will not only prevent foreign trade in airplanes, including some that has already become very profitable, but will seriously restrict the freedom of international travel by air.

Assuming general agreement on the proposition that protective measures should prevent themselves fairly as such, and that a qualified protection under the cloak of safety regulation is necessary, there are two possible procedures, but only one practicable one. First each nation may apply its own regulations to the imported machines at the source. Before the Aeronautics Branch was fully acknowledging the Canadian government arranged for its own inspection of the machines built for

Canadian order in the United States, and much more recently the British Air Ministry has had resident inspectors at least one plant in continental Europe. Oh, vividly that is a lure and holding expedient, not to be despised if on a grand scale. The Department of Commerce has quite enough trouble in the United States without attempting to keep its representatives in half the factories of Europe, passing on and controlling the machines that are to be shipped to America.

The other alternative is the working out of inter-governmental agreements for the mutual recognition of aeronautical certificates. It is upon that line that the Department of Commerce has been working, so far with very limited success. There is no want of air to negotiate, but a narrowly technical attitude will render any negotiations sterile. We may have one method of determining the stresses on the wing structure to a five, and the British or Germans, another. Such may be used, yet they differ, and if our technicians are allowed to argue the question they can debate it for seven years and never reach a conclusion upon which is the better. If mutual international recognition is to wait upon the development of identical standards of aircrafts the present generation will hardly see it accomplished.

There is one reasonable way, and only one. We counsel it not only to our own government, but to all the others of the earth. It is the way of the United States and Canada, whose aeronautical relations remain the absolute ideal. It is the way of mutual confidence.

As between any two of half a dozen governments that could be named, including our own, it is fair to pronounce that both parties want to make flying safe within their own boundaries. It is fair to assume that they have made a reasonably intelligent effort to do so, that the rules which they enforce upon their own industry reflect the results of that effort, and that they can be taken as a satisfactory equivalent of a totally different body of regulations built up in another country with the same fundamental aim. Then forget the technical questions. If the government of the United States and that of Great Britain, a European power with high standards of aircraft construction, will deal with each other on these lines we are sure that neither will ever regret it.

It only remains to be seen how many governments will have the courage to not admit the real logic that blocks them to their own facilities. We rely on the powers at Washington to lead the way.

//

Why Not?

AIRCRAFT, more than any other modern industry, has stirred the imagination and melted the ardors of industrial leaders in all branches of manufacturing endeavor. When keen industrial observers

close to discover in aviation the next big "mass production industry," it was not natural that they should such in their own way seek to unearth a channel. For the participation of their own organizations in this rapidly growing air industry. As a consequence, many organizations whose primary products are far from aeronautic, have affixed to themselves certain units which when made available to the aircraft industry as a whole, have introduced mass production methods and advantages far in advance of what the aircraft industry itself, acting through its many individual airplane manufacturing companies, could even dream of doing. Of the value of these contributions to aeronautical advancement there can be no question.

However, when a complex industrial situation reluctantly drives home the realization that the demand for particular designs of completed aircraft does not permit of the application of these same mass production methods to the fabrication of the entire plane, and in many instances temporarily does not even utilize existing special manufacturing facilities, isn't there a lesson to be learned by the airplane manufacturer himself? Just as other industries looked to aviation as a source of further utilization of mass production facilities already existing, why should not the airplane manufacturer look to other industries for the utilization of highly specialized manufacturing facilities now therein in need of orders to keep fully busy?

The airplane manufacturer has no ideal organization for the manufacture of special assemblies, especially in the light metals. He has modern equipment, highly skilled mechanics, and a research and design team. In mass production, of course, he cannot compare without extensive physical reorganization and readjustment, but when it comes to the custom-built luxury field he needs but a minor readjustment.

Without attempting to directly point out such possible extension of activity, but merely to crystallize and illuminate the thought, may we refer to light metal manufacturing as it might be applied to custom-built assemblies in the medical field such as racing shells, small harbor craft and powered pleasure boats, in the automobile field such as custom built bodies for pleasure cars, racing car bodies and special truck bodies, in the office equipment field for special built-in cabinets, files and furniture.

In addition to the physical facilities available for such special work, the very close contact for airplane sales is generally the best source of prospects for special luxury design.

The airplane manufacturer is by natural selection and training a man of resource and initiative. To bring these qualities to bear in the present situation will do much to maintain him as such, and to preserve intact the morale which is the very life of his organization. It appears that in some measure at least, turbulence would be fair play—as well as good business.

Mermos Shows the Way

HAVING BEEN invited in our opinion to discuss flying as a sport, it is with special pleasure that we lead the cheering for a trans-Atlantic performance out of the start dust. Almost as the third anniversary of the flight by which Lindbergh proved the possibility of a non-stop passage between the United States and Europe under favorable conditions, the pilot of the *Cougar* Aeroplane in whose honor we write has made the first aerial crossing between the States and the Western Hemisphere under something approaching commercial conditions. Though Mermos' voyage was infinitely less spectacular than those of Lindbergh, Charles G. Byrd, and Koebel, none of them outstrips it in real significance. For the lack of spectacular quality, indeed, the French company should be grateful. This is the one thing that a commercial serviceman can have. When it is necessary to keep customers upon the pilot's dining and conference we can be assured that the service will not long continue upon a regular schedule. If the successful completion of a flight upon a single non-stop calls for wondering airplane, the loss of probability are all against there being a leveler or a thousand successful completions is successful. The first condition of commercial operation is that we should be able to take the smooth functioning of any individual element for granted, deserving neither praise nor censure.

The greatest lesson that can be done to Mermos' flight, therefore, is to treat it not as a marvel in itself but as the inauguration of an indefinite series. Whether it will actually take out that way or whether, as in the case of the *de France* catapult experiment, the difficulties will prove more formidable than is anticipated and cause a temporary abandonment until better equipment can be developed remains to be seen. The undertaking is a bold one, but it has at least a fair chance of success.

Three years ago next month, when our *Affiliate* flight, —the flight—had been made and others were in prospect, when we were all a little hysterical, there was a profession of perfection that regular trans-oceanic service with mail and passengers was just around the corner. It is a long career, for there is little sign that we are nearing it yet, so far as the North Atlantic is concerned. The North Atlantic is a terrible story. With fewer storms, more constant winds, and a much shorter course, no longer in fact than that from California to Hawaii, it seems barely within the reach of possibility for regular operation with planes of the highest efficiency and with a little tail wind. Using seaplanes, and with three high-speed vessels maintained as a permanent mid-ocean patrol, the hazard is reduced to a point that makes it proper to try the venture, although the cost is obviously immense.

While we of the United States will feel some gratification that the attempt of the Pan-American

Company had established a regular aerial connection between our own territory and the southern capitals of South America before one was set out from Europe, as a national living and vital one admission for the Aeroplane undertaking, nor detract from the anxiety with which we wish them a complete freedom from troubles.

//

More Discussion and Less Roofing

THERE IS nothing as helpful to struggling lawmakers as a get-together with competitors for an interchange of views and ideas. Every industry has its various associations which convene now and then twice during the year, and much of the progress of these industries can be traced to discussion behind closed doors of the committee room.

In the aviation industry, though, there seems to be considerable room for improvement in conference work. Companies appeared to us at various times lead us to believe that even the majority is not getting maximum value from such conferences.

To begin with, it seems that the work of the convening conference is often stopped out ahead of time. Various individuals are asked to present papers on subjects sometimes suggested, but often left to the judgment of the individual. The result is that four-fifths of the meeting is taken up with the reading of papers, the contents of which may be extremely interesting, but is of no assistance to the man who has come hands-on of ideas for the opportunity to look over his problems with others who may be struggling under the same load.

In the opinion of many the last conference ever held in the aeronautical industry was the meeting of the industry with the Aeronautics Branch in Washington, D. C., in December, 1927. That affair was not a presentation of prepared papers. It was a general get-together that gave every attending member the feeling that he could not know many things that had been sticking in his mind. Every one had a chance to take part in the discussion.

Of recent months, though, conference meetings have not satisfied many of the attending members. They have prepared to discuss, occupied only to listen, and departed with their problems still in the unsolved state. To correct this situation we suggest that considerably less time be given to the reading of prepared papers, and that the conference be thrown open to general discussion of problems affecting the majority of those attending. This suggestion is by no means new. In fact it has been tried, and with great success. The trouble is that the idea is not being practiced more generally. It is our firm belief that if it were, considerably more would be accomplished and to the more complete satisfaction of those who expended time and money to be present.

OPERATING Short Haul AIR

*Air Ferries, Ltd., Operation Between San Francisco and Oakland
Record That Indicates Possibilities for This Type*

By CHARLES F. McREYNOLDS
Public Cost Editor of Aviation

WORLD-WIDE attention has been attracted to the operations of Air Ferries, Ltd. which inaugurated an amphibious service on Feb. 7, 1933, operating between San Francisco and Oakland across the water by open bay on a six-minute schedule from dock to dock. Keynote-Landing amphibious laylines have been used in this service, with a full-load capacity of seven passengers and two pilots. Dock arrangements have been even superior to the water ferries, with planes landing at Pier 5 on the San Francisco side, within one block of the Ferry Bldg. and Market St., while landings on the Oakland side are made at the foot of Franklin St., adjacent to the First and Broadway Railway Station and within three blocks of the Oakland City Hall. There have been no outstanding reasons for the swift notice which this service has received. It is the shortest and most frequent regularly scheduled air service in the world, and it has enjoyed a phenomenal volume of traffic 11,291 paying passengers being carried in the first 30 days of operation and 21,000 passengers in the first 60 days of operation. This is due to the fact that the service was started during the worst season of the year, from the slowdown of winter.

The outstanding success which has attended the service inaugurated by Air Ferries, Ltd., has led some officials to the possibilities of short-haul air service as they might be made to fit into the transportation pattern of many portions of the country. There have been other examples of similar services operating with success prior to the formation of Air Ferries, Ltd. which give us a picture of the broad possibilities of air ferry lines.

The first of these, Pacific Marine Airways, started operations between Los Angeles harbor and Catalina Island in the summer of 1932 using Curtiss flying boats operating across a 20-mile channel. This is said to have been the first regularly scheduled airline in the United States to operate consistently at a profit and is believed to be the oldest established commercial airline still in existence. Successful from the start, services over the Pacific Marine Airways route have been constantly expanded from year to year. This has been made possible by a tremendous volume of tourist traffic to Whaler's "Magic Isle," and is an example of passenger air transport efficiently applied to a specialized field. Pacific Marine Airways was taken over by Western Air Lines in June, 1933, and since that time the service has been further expanded by the addition of Keystone-

Landing amphibious planes which have been flown direct from the Western Air Express terminal near Los Angeles to Avalon harbor, California, then using additional time for the excursion. Booking flying boats have been placed in service at Avalon for short trips around the island and to supplement the all-seater service across the channel. From Jan. 1 to Oct. 31, 1933, this line carried 8,645 passengers at an average of 30 per day. While traffic is quite seasonal over this route, reaching a high peak during the months of June, July, and August

The San Francisco terminal of Air Ferries, Ltd.
Water landing operation.

FERRIES

*Has Established a Traffic
of Service*

when the planes average 82 round trips daily, the fares charged, \$10.00 each way, are high enough to assure profitable operations.

Primarily the first true "air ferry" service was that opened by Vero Goss, during the summer of 1929 between Seattle and Bremerton, Washington—a distance of approximately 12 mi. across Breckenridge Sound. Here, again, the service is quite seasonal and is based upon special local conditions in that during the summer months a large percentage of Seattle people go to the Bremerton resorts for the summer and thus greatly augment the number of workers who daily travel back and forth across the Sound. However, Goss established his service with Keystone-Landing amphibians and carried 1,800 passengers in the first two weeks and 20,000 passengers in the first five months of the service. The trip, which required an hour and a quarter by boat consumed but 15 min. by air ferry. The price was \$2.50 by air compared to \$9.42 by boat. Goss was the first to develop a fast ramp leading down into the water so that the planes could climb right up on the docks and discharge their passengers. The convenience and speed of this method of docking is far superior to any other and the novelty of it is a real asset to air ferry lines.

Goss carried a considerable quantity of freight, automobiles, fresh vegetables, flowers, etc., in addition to passengers and found the service quite profitable and practical to operate. Although the traffic is seasonal, both on account of the summer colony situation and the weather conditions during the winter it is profitable to maintain operation practically the year around across Breckenridge Sound and expansion of the service is planned for this summer.

Joseph J. Tyrone, Jr. and his associates, deserve great credit for the vigorous manner in which they have established Air Ferries, Ltd., among the transport systems of the San Francisco Bay region. However, it was inevitable that such a service would be developed in that territory because of the peculiarly favorable conditions facilitating the operation of air ferry lines. San Francisco is a city of remarkably equable climate, not subject to violent or prolonged periods of storm, and with high waterbars in temperature. During a certain amount of the San Francisco area may be considered very nearly ideal for the year around operation of aerostats.

Vero Ferry Route in the San Francisco Bay District

From the transportation standpoint the San Francisco area is divided into three major territories by the San Francisco Bay, rendering water ferries the major means of transportation for a majority of San Francisco citizens. The San Francisco citizen who wishes to reach the Marin County residential area on the northwest side of the Bay, or the industrial-residential areas on the east side of the Bay must take the ubiquitous ferry boat, an indispensable item in marketing but an inevitable stumbling block in the path of rapid transit. There are no trolleys beneath or bridges above the Bay as yet and despite much conversation it will probably be many years before there are such. In the meantime the Air Ferry offers a major solution to the problem of rapid transportation for countless thousands of persons who find it necessary to travel in and around the San Francisco Bay region.

As a Ferries, Ltd., started service with three Keystone-Landing amphibians. Second floating docks were installed at the Oakland and San Francisco terminals in order to permit the planes to lower their wheels and run up the ramps to a dry loading platform. By actual timing of every hundred docking operations the actual time from the moment that the Landing reached the water to the time that they had moved to the dock, climbed up and discharged one full load of passengers, them on another, rolled down into the water again and taken off, was found to be between two and three minutes. This is the secret of air ferry operation on the satisfaction of passengers, no time being wasted anywhere.

A further advantage of the ramp fact is that it reduces the dock crew needed and makes it almost impossible

to damage the plane, as it is so often done when mooring alongside the ordinary ferry docks, or pier.

Schedules of the air ferry service on the original San Francisco-Oakland route called for trips every 20 min. from 7:30 a. m. until 11:30 a. m., and then every 15 min. from 12 noon to 6:05 p. m. This route proved to be successful that a San Francisco-Valejo service was inaugurated on March 27, the earliest date that sufficient equipment was available. The Vallejo run calls for a plane departure every hour from San Francisco from 8:05 a. m. to 5:05 p. m., and from Vallejo every hour from 8:30 a. m. to 3:30 p. m. Vallejo is at the southern end of San Francisco Bay adjacent to the great Marin, Island Navy Yard and a large industrial district a distance of 22 mi. which is covered in 15 min. by air. The San Francisco-Oakland run, a distance of 40 mi. which is covered in an average hour between San Francisco and Oakland is 31.50 each way and between San Francisco and Vallejo it is \$3.50 each way. At a slight extra charge the planes flying on the Oakland run will land passengers at the Alameda or Oakland airports, thus making excellent connections with the various transport plane lines. Although no night service is now operated, due to the lack of adequate lighting equipment as well as to the lack of sufficient flying equipment for such constant service, such services are planned for the very near future.

Slow operating fuel Keystone-Looming amphibians, Air Ferries, Ltd., has a fleet of four more on order and plans have been perfected for the rapid expansion of the air ferry service to cover all important points of the San Francisco Bay region. Services are planned as early date to the following points, all of which during arrangements have already been made since each of these points is on the Bay or a large river. Sacramento 89 mi. from San Francisco, Stockton 83 mi., Richmond 9 mi., and Sausalito 6.5 mi. Another service is planned for

the towns of Sausalito, Palo Alto, and San Jose, all south of San Francisco with operations conducted from the San Francisco waterfront as land fields at each town named.

It is noted to be true that the 15,178 passengers carried during the first 30 days of operation were no more "top-heavy" but for the third of a single flight, Joseph J. Lyons, Jr., pres. arranged for a completed traffic check of all passengers carried during an average seven-day period after one month of service. The results showed that 71 per cent were traveling as business, that nearly 25 per cent had used the service before and were becoming "habitual" passengers, and that 23 per cent were using the air ferry in order to save time. While it is only noted that a large percentage of the early traffic was such a line should be of the company rather type, it is evident from the results of the questionnaire that much of the traffic is of a permanent and growing nature. Another significant fact is that during the first 60 days of operation 7,400 persons trusted themselves to air ferries who had never before been up in an airplane, thus demonstrating the confidence which the public has placed in this transport medium. The following percentages are the final averages for the seven-day period checked: Men—72.8 per cent, women—27.6, crossing bay on business—71.2, crossing bay on pleasure or social engagements—38.8, using air ferries to save time—22.1, using air ferries through necessity—70.9, used air ferry before—38.7, making first airplane flight—40.2.

A consideration of the above figures makes it apparent that a goodly portion of the traffic now being carried may be classed as "legitimate customers," persons who may be depended upon to patronize air ferries regularly. Some of the "legitimate" users already mentioned are physicians making heavy calls, attorneys appearing in

A large passenger ferry plane, the Pacific 846, over the town at the Oakland, Calif. waterfront during

courts on both sides of the Bay on the same day, attorneys who make personal contact, messengers and buyers for large firms which maintain branches in several of the Bay cities, ship captains who berth at Oakland but fly to San Francisco and back in order to arrange their papers and make it possible to berth at a full hour earlier and in general, of course, all persons who are in more of a hurry than usual. Since more than 110,000 people cross the Bay every day by water ferries it is evident that the air ferries have a vast traffic reservoir on which to draw. The best traffic control for Air Ferries thus far has been the carrying of 947 passengers on Sunday, Feb. 16.

COMMUTATION ROUTES are soon to be issued as a step toward building genuine commuter patterns. A further service planned is the handling of parcels in cooperation with established agencies. Already two San Francisco newspapers are sending their early morn and extra editions across the bay on the air ferry planes in order to get them on the streets of other Bay cities while the front-page headlines are still "hot off the press." Several hospitals have used the air ferries to make rapid errands across the Bay by messenger and this practice will no doubt become more and more common. A further factor which ensures the permanency of an air ferry service in the San Francisco Bay region is the happy manner in which it fits in with all rail, bus and air lines operating north, east, or south from the Bay District. Passengers on Boeing, Western Air Express, T.A.T. Middle, Air Lines, West Coast Air Transport, and Pacific Air Transport can save time both going and coming by patronizing Air Ferries. Transcontinental train travelers can cut approximately two hours from their journey by transferring to the Air Ferries plane at Vallejo. Other services soon to be

inaugurated will offer particularly advantageous connections with a number of important bus lines.

With a normal average of 76 loadings a day it is natural that there are many problems of operations technique to be faced. Air Ferries planes are based at the Oakland Airport, where a complete mechanical staff and shop is constantly engaged in inspecting and conditioning the planes in order that the rigid daily schedules shall not be interrupted. Naturally this requires that practically all mechanical work be done at night in order that the daytime flying may continue. Needless to say, the abnormal number of landings and takeoffs with full loads is a constant drain on both planes and engines and calls for extreme care in servicing. Loading areas are always open at Oakland, Alameda, and Vallejo, but the San Francisco waterfront becomes fairly rough at times and subjects the planes to real pinballshots. Because of the short route it is the practice to carry a small load of fuel, thus making it practicable to carry a full load of extra passengers. This practice calls for refueling as often as every three or four trips, the time spent in refueling also being used to advantage for the draining of any water which normal leakage may have allowed to seep into the hull, thus keeping the hull as light as possible at all times for greater efficiency. Although numerous ferry boats, river boats, and ocean steamers are constantly plying the waters of San Francisco Bay the water areas are so wide and the traffic is such a well-regulated and normal occurrence that no inconvenience has ever resulted. One danger is carefully watched and that is the presence of floating logs or drifters in the water across one's bow. Fast speed boats are provided with which to run down and pick up such obstructions and the dock crew, as well as the plane pilots, watch the water areas closely. These speed boats are also always available in case an emergency should arise requiring the rapid transfer of

An Air Ferries passenger landing up to 947 on the San Francisco-Sacramento air line.

passengers from the planes at some distance from the dock, or in the event of a minor fender bender that the plane be towed to the dock.

Wharf terminals are merely pier ends equipped with small offices such as any shipping company might use, with a fenced-off portion to separate spectators from passengers. Docks were originally large floats with floating ramps on shore rollers up which the planes could taxi while the passengers waited the runway to the pier on the fourth side of the float. New floats of special design have now been built and installed. These are of large, recent, overhead construction, the ramps being a rigid part of the entire float structure and extending well down into the water below the level of the plane's wheels when approaching. Such a float makes it much easier for the airplanes to climb the ramps under their own power. Incidentally, dock cranes are completely equipped with gaff hooks, goosenecks, and cables to draw the plane ashore a plane in the act of discharging the ramp. Two men can hold the plane on the ramp as an emergency while the passengers are loaded and a sea lead taken on via the emergency gooseneck. In the meantime the pilot re-verts the rigging and is ready to go without delay and with full light instruments to passengers.

At Oakland alone, Air Ferries, Ltd., is expending its service rapidly, based upon the outstanding acceptance which has been recorded in early statistics. By September of 1938 this company expects to have a fleet of 20 airplanes in regular service, between a total of at least a dozen central California cities and towns.

There are already 13 pilots regularly flying for Air Ferries, the largest active flying force permanently

Officers of the company include Joseph J. Tynan, Jr., president; J. G. Matthews, assistant to the president; and Marshall Hild, Harry S. Scott, Harmon S. Robinson, James Ralph Hill, Ted Higgins, Vern C. Gant and Connelly L. Moore, directors.

Although as has been outlined above, San Francisco is a particularly fertile field for the development of such a service as the air ferry, nevertheless it seems reasonable to believe that what the air ferries are doing for transportation in the San Francisco Bay region, they can do to some degree for at least 25 other American cities. In general it will be necessary for all such services to take advantage of water areas near the business district for landings, and some such docking as has been worked out by Air Ferries, Ltd., seems to be the solution to the problem where a close schedule is being maintained. However, it will probably prove practicable to operate air ferry services at many points which will not justify the volume of traffic or frequency of schedules which has characterized the San Francisco operation. Many population centers where large numbers of people travel some distance between work and home, or to yacht clubs, golf grounds, or hunting clubs will find the air ferry, even on an intermittent schedule, a valuable service once established.

It is general, it seems quite probable that the real possibilities inherent in short-haul air passenger carrying have been somewhat slighted. A check of traffic figures reveals that approximately 300 times as many people ride inter-urban transit systems every day as ride the longer cross-country routes, and that approximately 1,000 times as many ride on downtown rapid-transit systems to ride the cross-country lines. While we cannot hope to place airplanes in a sort of ground-town transit service, we should look forward to the time when a considerable portion of our population will ride back and forth from home to work via air in preference to surface travel. Such a development will come first with the airplane, and later with all types of planes. It will extend the radius of any one man's action, make it possible for him to work and play at greater distances from his home, and just as much successfully move rapid forms of transportation has enabled us to live, sit, and travel free from limitations of space and distance so we will possibly vastly improve our whole economic structure and see the airplane come into its own as a medium of transportation.

Certainly such a project seems to be sufficiently promising to hold legs and work for at the present time. It may be that we will find it possible to design planes specially suited to short-haul service which will lessen the aerial cost of such an idea. Designing for comparatively low speeds, the ability to hit heavy lands, obviously suggest landing gear, the elimination of much of the fuel load carried on longer flights, and the development of specialized docks and landing fields may give us ferry and mail plane services much easier and on a wider scale than many have heretofore dreamed would be possible. Traffic studies of inter-urban and mid-line cities of the American cities show 18 mph to be a good overall average speed for the routes covered. Such a figure is a direct challenge to the aviation industry and it is to be hoped that the success of Air Ferries, Ltd., in their San Francisco Bay operation, will be a direct and immediate impetus to the establishment of many more short-haul air services in this country.

MAKING Aerial Mapping PAY

Left to right, H. H. Franklin, pilot, and Maj. H. A. Erickson, photographer attached to their furnished C-47 transport.

By MAJ. H. A. ERICKSON
President, Erickson Flying Photographers, Ltd.

of miles from the base and with planes of high cruising speed considerable time may be saved in covering the area. Recently we flew for seven miles of coastline in California a job which required flight from each of which was 25 miles long. Here we flew from 250 to 275 miles daily. None of this will be discussed here, but I like the case here to indicate the necessity of having not only a powerful engine, but a dependable engine and plane of good characteristics. We employed a Waco-powered Fairchild.

Development of photographic equipment has kept pace with engine and aircraft development. Where 10 years ago we operated with plate cameras capable of handling possibly 48 plates during a single flight, now the camera used for mapping employs roll film on which 500 or more exposures may be made. We can make an unlimited number of exposures on a single run, operating as long as light will permit. It is easy indeed to make 800 exposures on a single mapping flight.

Equipment has advanced to such an extent that either in the field or in the laboratory the film can be handled immediately and prints made from it in a short time. We develop air film (800 exposures to a roll)

AERIAL PHOTOGRAPHY has advanced rapidly in methods during the last few years owing to improvements in equipment and the free advance made in design of planes and engines. In the early days we were limited to under tiny planes and later to the 10's with open cockpits. Now the aerial camera can be comfortable in an enclosed cabin plane.

In the air a decade ago it was difficult to obtain enough altitude to carry on a photographic mission. Now high we could go and how long we could remain at adequate altitude were not vital questions, each time we carried out for a photographic flight. Nearly two-thirds of our flying time was consumed in climbing to the desired elevation, which hardly ever exceeded five or six thousand feet. Today our elevation is not so limited and with the aid of oxygen mapping is being done at relatively high elevations sometimes 18,000 ft. or more.

Elevation of a mapping run generally is determined by the elevation of the ground, particularly in the west where ground levels may range in a short distance from sea level to 14,000 ft.; and it sometimes is necessary to be as much as 12,000 ft. above the ground elevation. With the present larger power plants and planes of increased load carrying capacity, however, altitude is reached in a short time. Moreover it may be maintained for several hours without returning to the ground for fuel.

Today photographic mapping may be done here and

Commercial aerial photography is a business in which many have become engaged, but relatively few have been successful. Among the first to attempt this sort of work was Maj. H. A. Erickson. His success needs no comment here, for it is well known throughout flying circles. In the accompanying article Major Erickson writes of the various problems that confront the aerial photographer, and of the methods that he follows in that his work will meet with the complete satisfaction of his client.

Lighting ramp with full-float-airline passengers and two pilots.

anchored in the San Francisco Bay district. These rates include a schedule of carefully known expenses. Stewart Manager is chief of operations, H. A. Reed, assistant chief of operations, while Charles McElroy Paul, Lieut. Charles G. Shaw, Bartlett Stephens, Monty Sharp Ray H. Varney, Jerry Valdivia, Ray Moore, Francis Sawyer George McCallahan, Vic Haganson, Leo Brigger, Fred Hammer, and James Haggerty complete the pilot group. A number of these men have had wide experience flying with the Vero Clinic air ferry service in Seattle.

by the Simons system which has been adapted by the U. S. Army and Navy and was used in the recent Alaska aerial survey by the Navy.

Film can be made ready for printing within an hour after developing has started. The reason of printing the film in the roll without entering the resources also expedites the process. In flying, also, the film remains in its original roll, requires less space and is more easily classified. Reducing is also handled on the roll and corrections are made for so-called "kink."

The mosaic work with the advanced equipment, beginning from the plate and power plant to the finished print, can be done rapidly. The photographs are easily made at a true vertical and at the desired elevation and require very little enlarging or reduction of the prints. Also in copying mosaics we have derived a camera which will use 35 mm film or glass plate up to 3000 in. in size. Again this camera is utilized to enlarge these negatives in order to get the reproduction back to the original scale.

The definition in the reproduction is remarkable. No detail is lost and one could easily believe the finished reproduction to be truly the original picture.

QUICKLY, all this equipment costs considerable money but it also expedites the work. We find usually that our clients want speed in production. For instance, they will call us up on Monday informing us that they want a certain area surveyed. We immediately fly to "headquarters" to get their maps showing areas desired, and by Tuesday evening, if the area is not very large, we are back at our home base ready to develop the film. On Wednesday the prints and mosaics are made and copies reproduced and on Thursday morning our clients have the finished job in their office. Speed of production and quantity of the finished work makes the impression which brings to the volume of our business.

Speed in completing the job and delivering the finished work together with a reasonably uniform quality was particularly important also for lingering in our office the largest oil mapping job yet attempted in the west. It became necessary first to attract a number of companies who were interested in the area general area by promising to them not only the economy but also the value of having a map of the entire district. As a result through the efforts of Mel S. Kennedy, in charge of aerial survey for the Texas Company, eight of com-

panies became associated in a survey of 2,300 sq. miles in four counties adjacent to Salinas.

The companies participating were the Texas Company, the Shell Company, Continental Oil Company, General Petroleum Corporation, Associated Oil Company, Union Oil Company, Rockfield Oil Company and the Western Gulf Oil Company.

When we began to undertake this large job, we determined that our product, the finished pictures and the finished mosaics, would be more accurate and show better detail if we made all operations as nearly mechanical as possible. At the outset, to guarantee uniformity, already we purchased a new Zeiss altimeter, the first altimeter of this type to be used commercially. We installed a vernier thermometer on the strut in such a position that it could be read from the cockpit. We also were furnished with a computer by which we were able to determine the difference between actual elevation and elevation as indicated by the altimeter.

Before taking off, a note was made of the thermometer reading, and on reaching the desired elevation as indicated by the altimeter, we again read the thermometer. Thus, our temperature on the ground may have registered 60 deg and the temperature at the outcrop should be 42 deg. We then adjusted the computer and determined the true elevation. The Zeiss altimeter would then be set at the actual elevation as desired for flying. By recording the reading hourly and noting any change in temperature, we were able to maintain constant elevation above the ground.

Naturally cameras on the ground level showed a difference of 700 to 5800 ft. above sea level, and if we were 12,000 ft. above the ground level it naturally was necessary to make exact readings to determine elevations. Fortunately we had a plane and engine sufficiently efficient and powerful to carry so rapid slope changes in constant flight. The area also was so large that if climatic conditions at one side did not permit flying we could move easily to the other side and continue our work successfully.

From our base at the Salinas Airman's Legion airport we flew 75 ft. 10 min., of which 63 ft. 30 min. were used in the survey proper. An average of 33 sq. miles was mapped per hour of flying. We made 5,400 exposures during 18 days of flying, delivering 30,000 prints in addition to mosaics to the various companies. Prints were made in 16 days, an average of 2,000 prints

per day. The job was completed in 10 weeks. Two K-5 aerial cameras were used. As the flying spans were 75 miles long it became difficult at times to see even half the length of spans. For this reason we carried a survey plane along. Irving Flaxner, an engineer with the Texas Company, served in this capacity and his expedition of United States Geological Survey sheets used for flight control was excellent.

Since our flight lanes were so long we were forced to use two cameras. At an elevation, 12,000 ft. above the ground level, our camera would photograph approximately 54 miles on one roll of film which was 75 ft. long, and on which 300 exposures were made. An area was used up in No. 1 camera, No. 2 camera would be

Pilot Flaxner and Major Kristman holding the finished film mosaic used on the survey.

put in place and operation continued on to the end of the flight. On reaching the end of a flight lane and while the pilot was maneuvering to get on his next line for the run back the camera with the exposed film was released and ready by the time the field was started. These flights were down back and forth but they were so long only four to six runs could be made in a single day. Fortunately we had perfect weather and in the time we were in the field only one day was lost due to cloudy weather.

Each night we dispatched the laboratory at San Diego, 500 miles distant, these rolls exposed during the day's work. In this manner we were able to develop as the job progressed and to ease any faulty film we discovered we could fly that part of the area again and thus avoid a long and expensive—both in time and money—flight at some later date.

As the contract called for a delivery of prints of the areas in which the various companies were associated, 12,568 sheets of paper were used, of which 30,000 were delivered. The percentage of waste was only .045 percent. This seemed to perfect printing was due largely to the use of the new Eastman 11514 printers in conjunction with the Palsdorp developing machine and the Gage Rooker system for fixing and washing. Also the drying was taken care of by use of the large double belt driers. It required only 16 days to make and deliver this large number of prints. A few weeks later the mosaics were delivered.

While the average interval between pictures was about 35 sec., sometimes intervals between exposures was only 2 sec., especially when we were flying with a strong tail wind. At 60 per cent overlap the horizontal and vertical verticals were required. Throughout the job these requirements were met. Not a single picture was lost

of true vertical and the average interval was maintained throughout with or against the wind.

This area had not been surveyed for oil geology from the air and through Mr. Kennedy the various companies interested were contacted to finance the survey. As a result, the survey was successful. The pictures and prints are utilized by the various companies by their field crews and in oil geology.

The photographer who materials to do a really good job of aerial mapping must contend with a number of things, especially if he hopes to obtain several different mosaics. First, the flying. The capabilities of the pilot, the power of the engine and cruising range of the plane are the principal accessories for good flying. If the pilot cannot fly in a straight line considerable results result. If the plane cannot reach the necessary ceiling the photographer has considerable more photographic work to do. These things are axiomatic.

THE MAPPING photographer depends for his success in a large measure on his pilot, and good photographic results are few and far between. The good photographic pilot has been successful through hundreds of hours of photographic flying. It may seem easy to the average pilot to go up with a photographer for "a few pictures," but after each flight he learns new angles about the game and soon realizes that the more he flies and the longer he flies, the more he knows. The more he knows, the more he is able to fly by his instruments, especially at high elevations. In making air maps the pilot must fly at an absolutely level and straight line over the area that the photographer may make parallel strips to use in with precision and future runs across the desired ground. By doing this he obtains the necessary overlap.

In any branch of air photography, the pilot should be experienced in photography. Manifestly his task becomes easier and he becomes more expert with experience. The pilot accustomed to "reporting in" his position for the use of the photographer, especially for map making, I never see a pilot who has less than 500 hrs. flying time. For an hour or longer, on the longer mapping jobs the pilot must be able to keep his course without vertical or horizontal deviation regardless of air currents. For example, if the pilot is flying over the Palsdorp Corporation, who served as my pilot while mapping these areas, could not have flown his parallel strips at an altitude of 12,000 ft., each 25 miles long, had he not had adequate prior experience. The pilot is too great to rely on an inexperienced pilot. The developed film shows series in the area, the photographer must fly again and help the pilot pick out these spots in the area for new pictures at the same altitude as previously flown.

One of the things greatly overlooked by a company in estimating the cost of aerial survey is the cost of flying. One may think that \$1,000 will pay for a certain job, but our experience has demonstrated that it is better to estimate the cost at three times that figure to be sure of covering the work at the end. Next is the film cost, and usually, if there is a number of prints, it makes much more film will be used and the cost of film is a considerable part of the total cost.

As far as the laboratory work is concerned, we find that the best available equipment is cheapest in the long run. Good equipment cuts down the time and helps clean up. If the laboratory is equipped in nearly mechanical as possible, quality of production is more uniform and satisfactory.

The Strip powered Palsdorp Cabin machines used by Major Kristman on his aerial survey on oil fields.

THE CURTISS Condor

Transport Plane Powered With Geared Conqueror Engine is Commercial Conversion of Military Machine

By LESLIE E. NEVILLE
Technical Editor of AVIATION

THE CURTISS Condor Transport, several of which are in daily operation in the service of T.A.T., is a commercial conversion of the Condor B-20 Bomber. Following a redesign of the military craft, the first commercial Condor was test flown during the Summer of 1937 and shortly afterward placed in T.A.T. service. Several minor modifications have been made in the past few months mainly with the object of increasing visibility for passengers, and the resulting model is now in production at the Garden City plant of the Curtiss-Wright Corp.

From the standpoint of Curtiss structural practice the Condor might be considered as conventional, except for its wing. Aerodynamically it is unusual because of the fact that it is a *high-wing*, whereas all but one of the other American transport airplanes at present available are *low-wing* planes. It is also exceptional in that it is probably

the only American transport at present powered with water-cooled engines, and that it is a two-engine rather than a three-engine land plane. The power plant consists essentially of Curtiss Geared Conqueror engines rated 600 hp, each at 2,500 r.p.m. Credit for the design is due mainly to T. P. Wright, chief engineer; George Page, and Alexander Noble, project engineer.

EXCEPTING the interior arrangements, the Condor Transport bears a marked resemblance to its military prototype. Engines are mounted in nacelles on the upper surface of the lower wing and as close as possible to the trailing structure with provision for adequate propeller clearance. Radiators are mounted above the nacelle and behind the engine with appropriately streamlined housings and shutter arrangements. The Condor has a wing span of 91 ft. 8 in., length overall of 57 ft. 6 in. and

Curtiss Condor and Ford Intermotor structure represent design employed in new Transcontinental Air Transport

height overall of 16 ft. 3 in. The weight empty, with 288 lb. of water, is 14,352 lb., of which 5,643 lb. is structure weight. The gross weight is 17,598 lb. and the type certificate weight 17,900 lb.

ALSO PREVIOUSLY MENTIONED, the wing structure conforms with Curtiss standardized practice and consists of a combination of steel and aluminum alloy. Spars are built in the form of a truss, the chord members being steel tubes drawn to elliptical section, and the web members round steel tubes. Chrome molybdenum steel is used throughout the highly stressed portions of the structure. Chord members of the spar are heat treated in lengths to a tensile strength of 140,000 lb. per sq. in., while reinforcing provides sufficient strength for the web members. In its welding process the joint is closely confined to the point of junction and does not affect the middle third of the span sections where stresses are high. The web members that are in tension pass outside through the chord members, while the others are secured to the inner surface of the chord members.

Ribs are made up of flanged tube drawn sections of aluminum alloy, while webs are of tubular section with flattened ends riveted to the flanged tube cap strips. It is interesting here to call attention to the characteristic Curtiss method of attaching the ribs to the spars. A small sheet steel lug, superimposed steel in length to the major axis of the elliptical section of the chord member is welded transversely to the chord member at two points. This forms a flat surface to which the flanges of the rib caps may be riveted with two rivets. The leading edge is finished with aluminum alloy sheet, while the wing tips are formed of tubular members of the same material. Drag bracing is of standardized Curtiss type. Fabric covering is employed for the outer wing and plywood walkways are provided for the lower wing outer sections between the fuselage and the engine nacelles.

Wings are of rectangular plan form and constant thickness employing the fuselage Curtiss C-73 airfoil section. The chord of each wing is 108 in. and the gap 126 in. Both wings are set at an angle of incidence of 1.5 deg. The upper wing dihedral is zero and the lower wing dihedral 3 deg., while the sweepback of both wings

is zero and the stagger in inches at the leading edge is also zero. The total wing area is 1,510 sq. ft., of which 238 sq. ft. constitutes the aluminum area. High incidence load factor is 4.5. An fuel tank the center of gravity is located at 33.7 per cent of the mean aerodynamic chord. Ailerons are constructed as a manner somewhat similar to the wing and an angular travel of 25 deg. upward and 25 deg. downward is provided.

The fuselage also conforms with the general structural practice of the Curtiss Co. and embodies a combination of chrome molybdenum steel and aluminum alloy. Longons are of 2 in. steel tubing through the main stations and represent the greatest diameter of any tube employed in the fuselage structure, while the intermediate transverse members are of aluminum alloy riveted to aluminum alloy cleats wrapped around the longons. Tubular rivets are used and applied cold. In order to avoid passing of fuselage members through window areas, the fuselage "K" bracing is riveted through the side sections, while a conventional Warren truss is employed in the tail. The anchored metal roof is built up of .025 aluminum alloy, while the cloth covering the fuselage sides is pressed into the edges of the metal material to provide anchorage in the covering process. Flushing is built up of wide channel members of aluminum alloy riveted together at right angles to each other.

The metal structure of the plane is protected externally through the use of red oxide primer and paint. Open holes are painted inside and all sealed tubes are treated internally with lacquer oil. Condenser pipes in engine oil for steel fittings and the aluminum fittings used in the cooling system are anodically treated.

AIRLINE COMMUNICATION BY

Telephone
Typewriter Service

Map showing the Eastern Air Transport line across the United States.

By GEORGE G. BREED

Executive Telephone and Typewriter Company

AIR TRANSPORT, like railroad operation, demands for its success upon the proper combination of its several units. For many reasons, this combination must be much closer, much more closely developed.

In the first place, air transport shares with the railroad its early problem of weather. In the beginning of railroad operation the weather played a part, the importance of which is seldom realized. Rain, snow and fog exercised a controlling effect upon schedules, and it did not take much knowledge of the wrong sort, to seriously cripple operations. Since it came in the very element in which the airplane operates, its importance to this new form of transportation is manifestly much greater.

Air transport is as a disadvantage beside the railroad in that its development is a matter of a very few years instead of decades. It has not that wealth of experience upon which the railway industry can draw. Further, it is dealing with much higher speeds and greater distances.

All these considerations necessitate a high degree of co-ordination. To achieve this the widely scattered peaks of the air transport company must have thousands of communications that are rapid, flexible and convenient; that permit a degree of co-operative effort approaching that achieved where all units are concentrated at a single point.

Eastern Air Transport, Inc., formerly Pitcairn Aviation, operates a daily line service along the Atlantic coast from New York to Florida. Connecting with major

air routes from the North and West, it handles an important part of the country's fast mail. The company makes every effort to maintain a operating speed of 100 mph.—involving an actual flying speed of over 110 mph.

This is a new mark to set in transportation. The railroad is operating on a schedule involving speeds—far faster passenger trains—of 40 to 50 mph. To achieve the results necessary where a speed twice this is being maintained, an air transport company must have instantaneous and continuous contact between its various units. Only in this way can the work of plane-dispatching be carried on efficiently and the many activities of the company be properly co-ordinated.

To establish this contact, Eastern Air Transport, Inc.,

Man getting weather reports via telephone typewriter.

A Description of the Equipment

A model demonstrating the use of telephone typewriter service placed in the New York Times by the New York Telephone Company.

Which Permits Instantaneous Communication Between All Stations

installed a telephone typewriter service along its New York-Atlanta run.

The telephone typewriter is in the nature of an electric typewriter operating over Bell System telephone lines. It is similar to the ordinary typewriter and is operated in the same way—words typed on one machine being reproduced simultaneously on one or more machines which may be near at hand or, as in the case of the Eastern Air Transport service, scattered along a 1,600 mile line.

THE SUMMARY of operation of the machine is illustrated on page 1127. The sending and receiving mechanisms are driven by powered motors running at approximately the same speed. When the typist depresses a letter key on the keyboard of the sending apparatus, the key lever strikes the sending side of the machine in the first selection bar and moves them either to the left or right depending on the code for the key depressed. The total number of possible combinations is 32 which allows for combination for each letter and additional ones to control certain machine functions such as shifting to print upper case characters, underlining, spacing, etc. In this diagram the first and third bars are shown displaced to the right joining the corresponding contacts in such a position that they can be closed when the cam rotates while the other contacts are left in a position which prevents their closing. This combination corresponds to the letter "S."

At the same time that the key lever strikes the selector bar, it also moves the universal bar down releasing a latch and allowing the sending cam shaft to rotate.

The contact lever labeled "C" controls the starting and stopping of the receiving mechanism. When no signal is being sent the receiving magnet is held open but when the sending cam shaft starts to rotate the switch contact opens, the receiving magnet armature is released and the coil for starting the selector can click into its through intermediate device not shown in sketch a flip arm and permit the five selector arms (only one of which is shown) of the receiving printer to rotate.

The first contact lever of the sending mechanism then

rides on the surface of its cam and drops into the latch thereby closing its contact and sending a closed circuit impulse over the line. The second contact is the combination shown will not close and the line circuit will be held open. As the cam shaft rotates further the impulses either open or closed, are transmitted in succession, while a locking device not shown in the diagram prevents any change in the selection set up until the revolution has been completed and the signal transmitted.

When the selector cam of the receiving mechanism shows in the diagram rotates sufficiently to strike the end of the code bar operating lever. By this time the armature is again attracted because the first impulse is coming over the line and we have assumed it to be a closed impulse. The armature and armature extension will then occupy the position shown in the figure. As the cam gives its code bar operating lever, the latter is rotated slightly on a concentric-circular camshaft carrying back with it the word, the right-hand end of which will strike the right-hand end of the armature extension. The word will be rotated clockwise in its print and when the cam projection moves to clear the operating lever, the word will move against the left end of the "T" lever in its return forward and move the code bar to the right.

In the case of an open circuit impulse, such as the second impulse, the magnet armature and the armature extension will be in their unoperated positions. The No. 2 word, not shown but directly beneath No. 1 word, when pulled back by the action of the selector can rotating the code bar operating lever, will strike the left end of the armature extension which is held down at each end so as to be common for all five words. The No. 2 word will then be moved counter-clockwise so as to engage the right end of the "T" lever and move the No. 2 code bar to its unselected position. In this manner each of the five code bars in succession is made to occupy either a selected or non-selected position determined by the code for the particular character to be printed.

The five code bars are also connected to correspond to the signaling code. For each operation of the printer the

THE BUYER'S LOG BOOK

This Log is prepared for the convenience of Airframe buyers as a service to enable them to be published for their use in the air and without any additional consideration. It is intended to be used in the air.

Onan Lighting Plant

AN ONAN LIGHTING PLANT is now manufactured by D. H. Onan & Sons, Minneapolis, Minn. The unit weighs 22 lb. and is equipped with 120 volt, 60 watt bulb. It is a portable unit, mounted on a cylinder head and mounted on a mounting of (120 volt) Onan & Sons, Minneapolis, Minn. It is available in 120 volt and 240 volt.

ONAN LIGHTING
PLANT

side of the gasoline components, thus being for the different grades of lubrication of the engine and the power engine and the power engine. The unit is mounted on a cylinder head and mounted on a mounting of (120 volt) Onan & Sons, Minneapolis, Minn. It is available in 120 volt and 240 volt.

A 5000 watt, power, aluminum plant, mounted on a cylinder head and mounted on a mounting of (120 volt) Onan & Sons, Minneapolis, Minn. It is available in 120 volt and 240 volt.

ONAN LIGHTING PLANT

Western Aircraft Magneto

MODEL 244 MAGNETO built by the Western Aircraft Magneto Corp., Seattle, Wash., is a portable unit, mounted on a cylinder head and mounted on a mounting of (120 volt) Onan & Sons, Minneapolis, Minn. It is available in 120 volt and 240 volt.

ONAN LIGHTING PLANT

Abrasive Metal Treads

ABRASIVE TREADS for the protection of the landing gear, as well as the landing gear, are now being manufactured by the American Abrasive Tread Co., Chicago, Ill. The treads are made of a special material, which is mounted on a cylinder head and mounted on a mounting of (120 volt) Onan & Sons, Minneapolis, Minn. It is available in 120 volt and 240 volt.

Aviation Service Truck

A NEW TYPE OF AVIATION TRUCK is now being manufactured by the Aviation Service Truck Co., Chicago, Ill. The truck is a portable unit, mounted on a cylinder head and mounted on a mounting of (120 volt) Onan & Sons, Minneapolis, Minn. It is available in 120 volt and 240 volt.

ONAN LIGHTING PLANT

Parachute Back-Pad

THE BACK-PAD Parachute Co. has developed a new detachable back-pad, which is mounted on a cylinder head and mounted on a mounting of (120 volt) Onan & Sons, Minneapolis, Minn. It is available in 120 volt and 240 volt.

IT'S COOL AT AIRTECH

One of a Series Describing Airtech Advantages

Refreshing summer coolness brought to Airtech from the blue Pacific makes each summer day a pleasant day. This constant springtime is an important factor contributing to the excellence of Airtech Training.

Rough air, delaying take-off, sudden thunder storms, when you run for the bar, are unknown to Airtech summer students. Instead you will find continuous days of peaceful coolness with each hour of flight instruction making definite progress towards winning your place in aviation.

Before you decide, consider this school of established leadership.

LINDBERGH FIELD SAN DIEGO

ANOTHER MANUFACTURER IN THE AVIATION INDUSTRY THAT USES SKF BEARINGS

THE PRATT & WHITNEY AIRCRAFT CO.

Equipped with the
highest priced
Bearing in the WorldBECAUSE SAFETY COMES BEFORE PRICE
P & W USE 42 SKF'S ON NEW "WASP JII."

A NEW member of the Pratt & Whitney family... the 100 H.P. "Wasp JII" motor is also equipped with 42 SKF Bearings... 42 of them. This motor operates at 2000 R. P. M., has a bore and stroke of 5 1/2" and takes displacement of 965 cu. in. In the group we see the pilot and Pratt & Whitney engineers just after a test flight in which the motor and 42 SKF Bearings successfully met all performance requirements.

In most industries there alone is the best test

of a bearing. The first few months of operation do not tell the story for the ultimate showing determines the real cost of the bearing. Yet, in aviation, years of industrial service are rolled up into a comparatively short period of time. This makes it all the more important not to jeopardize dependability. You cannot compromise safety in the air with price. And that is the basis for the choice of 42 SKF Bearings by Pratt & Whitney.

SKF INDUSTRIES, INC., 40 East 23rd Street, New York, N. Y.

280

EQUIPPED WITH THE HIGHEST PRICED BEARING IN THE WORLD

Means just this

SKF
Ball and Roller Bearings

That the manufacturer's name product is obtained also preferred payment for their bearings and less for servicing or replacing them. They preferred to pay higher price in the beginning than maintain this higher price in the end. And, finally, they preferred to economize by using SKF bearings because they are made to do their job, not to fix a price tag.

"HORNETS" FLY 51,000 HOURS...

WITH BOEING

Boeing and plane... one of several types employed by Boeing for mail and passenger transport. Hornet engines and exhausts.

In the service of the Boeing air transport companies, "Hornet" engines have completed over 51,000 hours of flight. Of the 50 "Hornets" in Boeing service, carrying passengers and mail on each day and night schedules, 15 have over 1000 hours to their credit. And one has completed over 1,675 hours in the air.

These veteran "Hornet" engines, like their famous running mates, the "Wasp" and the "Wasp Junior," thrive under the unyielding requirements of dependable flying. They make good the promise of dependability and reserve power which has its source in Pratt & Whitney design, materials and craftsmanship.

MOTO METER AVIATION INSTRUMENTS

CHARACTER

IN FLEETS—as in other realms it is quite universally character that counts. Character is a word very hard to define, but that mostly makes it easier still not from the general run.

If inanimate objects of all have something that may be called character, the Moto Meter line of aviation gauges has it in profusion. It is not also the character of the organization behind them that counts.

For nearly twenty years Moto Meter has made fine instruments. It has pioneered them and

with them become standard equipment. It has devoted constant effort toward making them simple, reliable and positive in operation.

Small wonder then that Moto Meter aviation instruments (some of which are illustrated below) are found on the panels of the big air liners, of much smaller commercial private and service craft, and of the experimental planes that have carried so many names to fame.

Moto Meter aviation instruments in the pilot's cockpit are a sign of character.

Model 2823A Oil Pressure Gauge
(Pressure in psi)
Built to meet clearance and other
conditions in an aviation application.

Model C Fuel Heat Indicator
(Clearance in psi)
The fuel indicator of the Moto
Cylinder is a pressure indicator.

Model CA Ice Warning Indicator
(Clearance in psi)
Built to meet other aviation conditions. See

TRAVEL AIR AND ROBIN—
PAY THEIR OWN WAY

for

"CONOCO"

The "Conoco" III—a Robin Cabin Monoplane

THE value of Curtiss-Wright planes to business and industry is well illustrated in the service of Continental Oil Company.

"Continental Oil has found that aviation pays its way. It is not a fad or fettle, but an essential adjunct to good business management. Time saved is money saved, and, as a result of airplane travel, Continental Oil Company saved some 15 days of executive time during one month. On several occasions, airplanes have been used to avoid delays that would have meant the loss of thousands of dollars in trade oil and gas, and might have resulted in heavy destruction of property."

Thus does Mr. B. J. Moran, president, describe the service rendered by the Conoco III, a 6-place Travel Air monoplane, and Conoco III, a 3-place Challenger Robin.

During a promotion campaign, the Travel Air carried four company executives on a 5,000-mile tour, making 32 stops for sales meetings. On this one tour, it was estimated that use of the Travel Air represented a saving of \$2,000 over any other means of transportation.

The 3-place Robin is assigned to Mr. G. M. Bounds, aviation sales manager, "not as a passenger ship, but to use just as the jobber salesman or dealer salesman uses his automobile." Not only has the Robin proved itself indispensable in covering a large sales territory, but its smart appearance has a decidedly advantageous effect in making aviation sales.

The Conoco planes are constantly used when

emergencies demand quick action. They have carried experts from Oklahoma to California to cap a "wild" gas well. A break in a cross-country pipe line, from which gas escaped at a rate of \$5,000 daily, was discovered from the air in exactly 14 minutes flying time.

The Travel Air 6-place cabin monoplane, powered with the 500 h. p. Wright Whirlwind engine, has a high speed of 135 m. p. h., and a cruising range of 430 miles. It is a handsome ship, built for business, roomy, comfortable, dependable, economical.

The Robin 3-place cabin monoplane with 185 h. p. Challenger engine, sister ship of the famous record holder, the "St. Louis" Robin, attains a high speed of 118 miles an hour and has a cruising range of 525 miles. Smart, swift, modern to the minute, the Robin is the last word in comfort, combined with economy of upkeep and operation.

Curtiss-Wright will gladly furnish complete details on the Robin and Travel Air cabin monoplanes, their adaptability to particular needs, and actual cost figures of operation and maintenance. Address Dept. T. R-75

Ray Stender, Frank Moran, E. C. Macdonald, and B. J. Moran, sales manager, standing on a 2000-mile sales promotion tour in a Travel Air Cabin Monoplane (Conoco III)

PILOT RADIO SEVEN AMERICAN
GOODWILL FLIGHT
FROM NEW YORK TO BERMUDA
JUNE 1, 1935

NOTICE: THE NEW YORK TIMES—HAS REPORTED AFTER TWO HOURS OF FLIGHT
NEW YORK TIMES
NEW YORK, N.Y.
PLEASE TELL EDO THAT FLIGHT WAS SMOOTH
WENT WELL IN YOUR LAST FLIGHT
THANKS
EDWARD

EDO FLOATS

NIGHT in the Gulf Stream... a sturdy seaplane heaves and lurches with the churning, surging swell... dark waters charge and swirl across the EDO Floats that shoulder the cabin high above the reaching waves... each man, in turn, stands watch as his two companions sleep... an ocean liner draws close, but still is declined... down and a rising sea... a takeoff through the foam... then a radio message flashes across the 700 miles to New York: "Please tell EDO their floats sure showed what was in them last night."

This was a thrilling part of the epic flight—the first time a plane had ever flown from New York to Bermuda—the first plane ever to land in open ocean on a long flight and again resume the air after a night spent at sea.

The "Pilot Radio," a Stinson cabin monoplane, Wright Whirlwind-powered and equipped with standard EDO Floats, took off heavily loaded from Long Island Sound at 9:37 A. M., April 1st, and laid its nose on a lee-line for Bermuda. Capt. Lewis Yancey, navigator and veteran of one trans-Atlantic flight was in charge. Wm. Alexander, master pilot, had the controls, and Zeh Souck, radio expert, handled all communications. Messages of progress were continually broadcast. But due to an unavoidable delay at the start, their goal was not

sighted by evening. Rather than risk a landing in an unlighted harbor, it was decided to trust in EDO Floats and ride the sea for the night. No wind retarded the ship and the floats took the full 55-mile landing impact on the 15-foot wave crests.

The sea was rougher at dawn, but with EDO Floats and skilled handling, the ship rose swiftly and surely, in less than an hour the tiny spot of land to which Capt. Yancey had laid a straight course, came rolling over the horizon, and with it calm, sheltered water—and triumph!

As long as the ocean rolls, honest handwork will merit success. These men put their trust in EDO Floats and found them not wanting. For EDO Floats, from struts to futed bottoms, came through the test 100% perfect.

EDO Floats are manufactured in 11 models for the conversion of more than 40 distinct types of land planes up to \$250 lbs. gross weight. They are approved by the U. S. Department of Commerce, and recognized everywhere as the standard of commercial airplanes.

Airplane manufacturers, transport operators and private owners who have not availed themselves of the services of the experienced staff of EDO engineering specialists, are cordially invited to do so. Address, Edo Aircraft Corporation, 890 Second Street, College Point, L. I.

FEATURES TO REMEMBER ABOUT EDO FLOATS

All round construction.
Protected from corrosion.
Will not swell, shrink or absorb water.
Bolt-headed with a rust-free protection.
Protected futed bottoms for lightest load.
Heavy keels, shallow struts for heaviest float decks for ease of taking on loads.
Interchangeable with wheel landing gear.
Easy to install and overhaul.

Verville

Standardizes on HEYWOOD STARTER

THE VERVILLE AIRCRAFT COMPANY
DESIGN AND BUILD AIRCRAFT
STANDARD
March 8, 1935

The Heywood Starter Corporation,
1015 East Avenue,
Detroit, Michigan.

Dear Mr. Verville:

We are enclosing a photograph of the Heywood Starter which shows Mr. Verville has selected the Heywood Starter for installation on his airplane.

We thank you for the opportunity to see the Heywood Starter and its installation on the airplane.

We wish to thank you for the opportunity to see the Heywood Starter and its installation on the airplane.

Very truly yours,
THE HEYWOOD STARTER CORPORATION
1015 East Avenue
Detroit, Michigan

Following the practice of holding their product according to the last word in aeronautical advancement, Verville has equipped this latest incarnation of the Air with the Heywood Starter.

In keeping with the history of the Verville design the Heywood Starter adds the convenience and comfort of starting from the cabin seat.

And Heywood's non-falling start, its instantaneous response to a pull on the starter trigger, its sure performance in all kinds of weather—all of these qualities serve to add to the performance for which Verville is justly famous.

SKY SPECIALTIES CORPORATION

Start-er by Heywood

POWER EQUIPMENT for Aircraft Radio

ECLIPSE

DOUBLE VOLTAGE VOLTAGE-REGULATED RADIO GENERATOR ENGINE DRIVEN TYPE

The constantly increasing use of Aircraft Radio and the necessity for battery installations to take care of accessories such as navigation lights, landing lights, electric starters, etc., has necessitated development of a means whereby the current required for operation of all this equipment may be produced by a single unit. Eclipse Double Voltage Generators have been especially designed and developed to meet this aircraft requirement.

AVIATION DYNAMOTOR

The Dynamotor is especially recommended as a power supply for long range aircraft transmitting sets. Designed for use in conjunction with the Eclipse 50 Ampere 15 Volt Engine Driven Generator, the Dynamotor provides power for radio operation in the air—or for a limited time on the ground—a highly desirable feature in the event of a forced landing.
